Summary

Phased array noise source localization have been compared with 2 types of flow field data (BOS and PIV).

The data show that

- 1) the higher frequency noise in a BBSN hump is generated further downstream than the lower frequency noise. This is due to a) the shock spacing decreasing and b) the turbulent structure size increasing with distance downstream
- 2) BBSN can be created by very weak shocks.
- 3) BBSN is not created by the strong shocks just downstream of the nozzle because the turbulent structures have not grown large enough to match the shock spacing.
- 4) The point in the flow where the shock spacing equals the average size of the turbulent structures is a hot spot for shock noise.
- 5) Some of the shocks responsible for producing the first hump also produce the second hump.
